# VAPOR PRESSURE OF $\mathrm{He}^{3}-\mathrm{He}^{4}$ MIXTURES IN THE $0.7-1.3^{\circ} \mathrm{K}$ TEMPERATURE RANGE 

## V. L. VVEDENSKIĬ and V. P. PESHKOV

Institute of Physics Problems, USSR Academy of Sciences
Submitted April 27, 1972
Zh. Eksp. Teor. Fiz. 63, 1363-1370 (October, 1972)
The vapor pressure of $\mathrm{He}^{3}-\mathrm{He}^{4}$ mixtures is measured at temperatures between 0.7 and $1.3^{\circ} \mathrm{K}$ for $\mathrm{He}^{3}$ concentrations in the liquid up to $5 \%$ and for the complete range of He concentrations in the vapor. A dependence of the Henry law constant on temperature $\mathrm{a}=4.75(1 / \mathrm{T}-0.17)$ is obtained between 0.7 and $2.0^{\circ} \mathrm{K}$. A table listing the dependence of vapor pressure on temperature and concentration of gas phase is presented. The parameters of the excitation spectrum in dilute solutions of $\mathrm{He}^{3}$ in $\mathrm{He}^{4}$ are calculated: $\Delta=-2.65 \pm 0.1^{\circ} \mathrm{K}$ and $\mathrm{m} * / \mathrm{m}_{3}=2.8 \pm 0.2$.

IIN connection with the extensive use of helium-isotope mixtures in physical experiments, it is necessary to have exact data on the liquid-vapor phase diagram of the $\mathrm{He}^{3}-\mathrm{He}^{4}$ system down to the lowest temperatures. The diagram was determined by a number of workers ${ }^{[1-4]}$, but for temperatures below $1.2^{\circ} \mathrm{K}$, down to the lamination region of the solutions, there are only the data of Sydoriak and Roberts on the vapor pressure over a liquid with concentration $10-90^{\circ} \mathrm{He}^{3}$ (molar). In the lamination region, there are also the data of Goellner and Meyer ${ }^{[5]}$ in a narrow concentration range near the junction of the $\lambda$ line with the lamination curve.

The purpose of the present study was to determine the vapor line of the diagram, i.e., the dependence of the pressure on the gas-phase concentration, and also to determine the vapor pressure over a liquid with low concentration of $\mathrm{He}^{3}$, where the pressure increases most rapidly with the concentration.

A diagram of the apparatus is shown in Fig. 1. The mixture chamber 1 and the coolant chamber 2 were machined from a solid piece of copper, and their surface was further enlarged by using posts of $2 \times 2 \mathrm{~mm}$. The mixture chamber had 50 mm diameter, 50 mm height, $23.7 \mathrm{~cm}^{3}$ volume, and $\approx 200 \mathrm{~cm}^{2}$ surface. The parasitic heat inflow at $0.7^{\circ} \mathrm{K}$, determined from the temperature rise in the chamber in the course of time with the evacuation turned off, was $10^{-4} \mathrm{~W}$. With such an enlarged surface, the unevenness in the temperature in the mixture chamber, due to the heat inflow, was less than $10^{-4}{ }^{\circ} \mathrm{K}$. The relative change of the concentration over the volume, as the result of thermo-osmosis ${ }^{[6]}$ did not exceed $0.5 \%$ in this case. A temperature $0.7-1.3^{\circ} \mathrm{K}$ was obtained by pumping off $\mathrm{He}^{3}$ or $\mathrm{He}^{4}$, and could be maintained for an hour within $\pm 0.003 \% \mathrm{~K}$. The temperature was measured with two phosphor-bronze thermometers of $30 \mu$ diameter. One was suspended in the chamber and made contact with the liquid only, while the other was fastened to the chamber on the outside. The thermometers were calibrated in the chamber itself against the vapor pressure of $\mathrm{He}^{3}$ (1962 scale) and $\mathrm{He}^{4}$ ( $\mathrm{T}_{58}$ scale). The calibration accuracy was $\pm 0.002^{\circ} \mathrm{K}$. Once equilibrium was reached, the readings of the thermometers in the course of the measurement were equal within $(3-4) \times 10^{-3}{ }^{\circ} \mathrm{K}$.

The mixture consisted of natural $\mathrm{He}^{4}$ and $\mathrm{He}^{3}$ with not more than $10^{-5} \mathrm{He}^{4}$. The relative error in the con-

centration of the mixture did not exceed $1 \%$ for small concentrations and $0.5 \%$ for intermediate ones.

Precision measurements of low pressures were made with an oil manometer, the second bend of which was connected with a carbon adsorber in liquid nitrogen. The calibration was against a mercury manometer, and the ratio of the mercury and oil columns was $15.4 \pm 0.1$. The null of the manometer was regularly verified by evacuation to a pressure below $10^{-3} \mathrm{~mm} \mathrm{Hg}$. The shift did not exceed $2 \mu \mathrm{Hg}$. The pressure was read with a cathetometer accurate to $3 \mu$. Such a system made is possible to measure low pressures with the accuracy needed to observe very small kinks on the filling isotherm when determining the dew point for a gas with a large $\mathrm{He}^{3}$ concentration.

The manometer tube 4 leading to the chamber consisted of two parts. A thin tube of 1.6 mm diameter in the helium-temperature region, up to the top of the copper spherical $\mathrm{He}^{4}$ container, was followed by a thick tube of 20 mm diameter in the region of the transition to room temperature. Such a geometry made the thermomolecular pressure difference negligible in the measurement range, less than $0.5 \%$ according to Roberts and Sydoriak ${ }^{[7]}$. The main source of error was distortion of the pressure by the evaporating superfluid film. A control experiment has shown that the error due to the evaporation of the film did not exceed the measurement error down to a pressure 0.3 mm Hg , but increased catastrophically with further decrease of pressure. It was this circumstance which determined the lower limit of the measurement range.

*The notation is the same as in Table III.
place at very high $\mathrm{He}^{3}$ concentrations. An estimate shows that the $\mathrm{He}^{4}$ concentration at the kink point is less than $0.5,0.2$, and $0.1 \%$ for $0.8,0.7$, and $0.6^{\circ}$, respectively.

We have also measured the vapor pressure over liquids with small concentrations of $\mathrm{He}^{3}$ in $\mathrm{He}^{4}$, namely $0.98,1.92,2.88$, and $4.79 \% \mathrm{He}^{3}$. The results are given in Table II. The obtained data enable us to calculate the Henry-law constant a (Fig. 4)

$$
\begin{equation*}
P_{x}=P_{6}\left(1-x_{3 \mathrm{~L}}\right)+a P_{3} x_{3} \mathrm{~L}, \tag{4}
\end{equation*}
$$

where $x_{3} L$ is the $\mathrm{He}^{3}$ concentration in the liquid. The plot shows good agreement with the data for high temperatures (1) and (2), and with the interpolation proposed by Sydoriak and Roberts ${ }^{[4]}$ from the $10 \%$ concentration. It turned out that the Henry-law constant depends linearly on the reciprocal temperature in the $0.7-2.0^{\circ} \mathrm{K}$ range:

$$
\begin{equation*}
a=4.75(1 / T-0.17) \tag{5}
\end{equation*}
$$

(it is represented by the solid line in Fig. 4).
Tables III and IV were constructed on the basis of the derived formulas (3) and (5) and on the basis of the data of Sydoriak and Roberts ${ }^{[4]}$. Notice should be taken of the good agreement between the vapor line of the diagram described by formula (3) and the previously calculated ${ }^{[10]}$ vapor line.

The results can be used to calculate the constants $\Delta$ and $m^{*}$ in the law of excitation dispersion in a weak solution of $\mathrm{He}^{3}$ in $\mathrm{He}^{4[11]}$ :

$$
\begin{equation*}
E=\Delta+p^{2} / 2 m^{*}, \tag{6}
\end{equation*}
$$

where $E$ is the energy and $p$ is the excitation momentum. The chemical potential of $\mathrm{He}^{3}$ in the solution is

$$
\begin{equation*}
\mu=\Delta-T \ln \left[\frac{2}{x_{3} \mathrm{~L} n_{4}}\left(\frac{m^{\cdot} T}{2 \pi \hbar^{2}}\right)^{3 / 2}\right] \tag{7}
\end{equation*}
$$

where $\mathrm{n}_{4}$ is the number of $\mathrm{He}^{4}$ atoms per $\mathrm{cm}^{3}$. Equating it to the chemical potential of the $\mathrm{He}^{3}$ in the gas ${ }^{[9]}$, we obtain

$$
\begin{equation*}
\ln \frac{N_{\mathrm{V}}}{N_{\mathrm{L}}}=\frac{\Delta}{T}-\frac{3}{2} \ln \frac{m^{\cdot}}{m_{3}}, \tag{8}
\end{equation*}
$$

To prevent evaporation of the $\mathrm{He}^{3}$ from altering the low $\mathrm{He}^{3}$ concentration, the chamber was filled in such a way that the low-temperature gas volume was small (less than $1 \mathrm{~cm}^{3}$ ), not more than $2 \%$ of the $\mathrm{He}^{3}$ in the liquid turned into gas at pressures below 4 mm Hg and at the minimum concentration. This was done by condensing in a chamber of known volume ( $23.7 \mathrm{~cm}^{3}$ ) a strictly determined amount of gas from a flask of known volume ( 25.00 liters), as monitored by the pressure in the flask. The volume of the liquid mixture was calculated by using the data of Ptukha ${ }^{[8]}$ on the density of liquid solutions of $\mathrm{He}^{3}$ in $\mathrm{He}^{4}$.

We measured the dew points down to $0.85^{\circ} \mathrm{K}$ for concentrations $32.2,66.8,91.3,95.44,97.60,98.59$, and $98.55 \% \mathrm{He}^{3}$ in the vapor. The results are listed in Table I. The indicated error is the error in the determination of the position of the kink in the gas amountpressure isotherm in each individual experiment.

For a solution, assuming the vapor to be ideal, we have the thermodynamic equation ${ }^{[9]}$

$$
\begin{equation*}
1-\frac{x_{3} \mathrm{~L}}{x \mathrm{~V}}=-\frac{\partial \ln P}{\partial \ln x_{4 \mathrm{v}}} \tag{1}
\end{equation*}
$$

where $x_{3 L}$ and $x_{3} V$ are the molar concentrations of the $\mathrm{He}^{3}$ in the liquid and in the vapor, and $\mathrm{x}_{4 \mathrm{~V}}=1-\mathrm{x}_{3} \mathrm{~V}$. At temperatures below $1.3^{\circ}$ the vapor can be regarded as ideal. In addition, in a large range of $\mathrm{He}^{3}$ concentrations in the vapor (up to $\mathrm{x}_{3} \mathrm{~V} \lesssim 0.9$ at $1^{\circ}$ ), we have $\mathrm{x}_{3 \mathrm{~L}} / \mathrm{x}_{3} \mathrm{~V}$ $\ll 1$, so that the following expression is valid in this range:

$$
\begin{equation*}
P=P_{\mathrm{s}} / x_{\mathrm{sv}}, \tag{2}
\end{equation*}
$$

where $P_{4}$ is the pressure of pure $\mathrm{He}^{4}$ at the same temperature.

For high $\mathrm{He}^{3}$ concentrations in the vapor, close to $100 \%$, our data together with the data by others ${ }^{[1,2]}$ enable us to determine the dependence of $\left(P_{3}-P_{x}\right) / P_{3} x_{4} V$ on the reciprocal temperature, where $P_{x}$ is the pressure of the mixture and $\mathrm{P}_{3}$ is the pressure of pure $\mathrm{He}^{3}$ at the same temperature, approximately equal to the value of $\partial \ln \mathrm{P} / \partial \mathrm{x}_{4} \mathrm{~V}$ at $\mathrm{x}_{4} \mathrm{~V}=0$ (Fig. 2). This dependence coincides with the dependence of $0.3 \mathrm{P}_{3} / \mathrm{P}_{4}$ on the reciprocal temperature, where $P_{4}$ and $P_{3}$ are the pressures of pure $\mathrm{He}^{4}$ and $\mathrm{He}^{3}$.

FIG. 2. $\left(P_{3}-P_{X}\right)-x_{4}{ }^{2} P_{3}$ vs the reciprocal temperature at high $\mathrm{He}^{3}$ concentrations: $\mathrm{O}-1.45$ and $1.41 \% \mathrm{He}^{4},-2.4 \% \mathrm{He}^{4}, \Delta$-data of [ ${ }^{1}$ ]; $X$-data of $\left[{ }^{2}\right]$; the straight line is a plot of $0.3 \mathrm{P}_{3} / \mathrm{P}_{4}$ against the reciprocal temperature.

FIG. 3. Temperature dependence of the pressure for different concentrations of the gas phase. - O -present work, $\Delta$-data of [ ${ }^{1}$ ], $\mathrm{He}^{3}$ concentrations 58 and $78 \% ; X-\left[{ }^{2}\right] . \mathrm{He}^{3}$ concentrations $35.4,57.6$, and $82.4 \%$; $\square-\left[^{3}\right], \mathrm{He}^{3}$ concentrations 94 and $97 \%$. Solid lines-calculated from formula (3).

FIG. 4. Temperature dependence of the Henry-law constant. Data for the following $\mathrm{He}^{3}$ concentrations: $\Delta-0.5 \%$; $-1.0 \% ; \mathrm{O}-1.9 \%$, $\square-$ $2.9 \%, \mathrm{X}-4.8 \%$;-data of [ ${ }^{1}$ ], dashed-data of [ ${ }^{2}$ ], dash-dot-[ ${ }^{4}$ ].

Knowledge of the behavior of the curve in the two mentioned regions enables us to propose an interpolation formula for the vapor line on the liquid- vapor diagram of $\mathrm{He}^{3}-\mathrm{He}^{4}$ mixtures:

$$
\begin{equation*}
P=P_{\mathrm{t}} /\left[x_{\mathrm{tv}}+\frac{P_{\mathrm{t}}}{P_{3}} \exp \left(-0.7 x_{\mathrm{tv}} \frac{P_{3}}{P_{\mathrm{t}}}\right)\right] . \tag{3}
\end{equation*}
$$

The curves calculated by means of this formula for different concentrations are shown in Fig. 3. The experimental data of the present paper and the data of ${ }^{[1-3]}$ agree well with the calculated curve up to $1.8^{\circ}$, where the gas ceases to be ideal and formula (1) no longer holds ${ }^{[2]}$.

The interpolation curve proposed for the vapor phase diagram differs qualitatively from the real curve in the

FIG. 5. Determination of the excitation parameters $\mathrm{m}^{*} / \mathrm{m}_{3}$ and $\Delta=$ $d \ln \left(\mathrm{NV}_{V} / \mathrm{N}_{\mathrm{L}}\right) / \mathrm{d}(\mathrm{l} / \mathrm{T})$ in weak $\mathrm{He}^{3}$ solutions.
where $\mathrm{N}_{\mathrm{V}}$ is the number of $\mathrm{He}^{3}$ atoms per $\mathrm{cm}^{3}$ of gas, $N_{L}=x_{3} L^{n_{4}}$ is the number of $\mathrm{He}^{3}$ atoms per $\mathrm{cm}^{3}$ of liquid, and $\mathrm{m}_{3}$ is the mass of the $\mathrm{He}^{3}$ atom. From the data on the density ${ }^{[12]}, \mathrm{n}_{4}=0.22 \times 10^{23} \mathrm{~cm}^{-3}$ at a temperature below $2^{\circ} \mathrm{K}$

$$
N_{\mathrm{v}}=0.97 \cdot 10^{19} P_{\mathrm{part}} / T,
$$

where $P_{\text {part }}$ is the partial pressure of the $\mathrm{He}^{3}$ determined on the basis of data on the vapor line of the diagram. Figure 5 shows a plot of $\log \left(\mathrm{N}_{\mathrm{V}} / \mathrm{N}_{\mathrm{L}}\right)$ against the reciprocal temperature, from which we get

$$
\Delta=-2.65 \pm 0.1^{\circ}, \quad m^{*} / m_{3}=2.8 \pm 0.2
$$

This value of $\Delta$ agrees with the value $-2.68^{\circ} \mathrm{K}$ for concentrations smaller than $4 \% \mathrm{He}^{3}$ and temperatures $0.6-1.0^{\circ} \mathrm{K}$, calculated $\mathrm{in}^{[13]}$ on the basis of the vaporpressure data of Sydoriak and Roberts ${ }^{[4]}$.

The effective mass averaged over the range $0.7-1.4^{\circ} \mathrm{K}$ exceeds the values obtained for temperatures below $0.6^{\circ} \mathrm{K}\left(\mathrm{m} * / \mathrm{m}_{3}=2.2-2.5\right)^{[14-16]}$. This can be attributed to the increase of $m *$ with increasing temperature, as indicated in ${ }^{[16,17]}$. It must be noted, however, that there are appreciable discrepancies between the values of $\mathrm{m}^{*}$ given by different authors ${ }^{[18]}$.
